

Repetitions

You are given a DNA sequence: a string consisting of characters A, C, G, and T. Your task is to find the longest repetition in the sequence. This is a maximum-length substring containing only one type of character.

Input

The only input line contains a string of n characters.

Output

Print one integer: the length of the longest repetition.

Example

Input: ATTCGGG

Output: 3

Approach

The problem can be solved by maintaining a running count of contiguous characters. Iterate over the string, and for each character check whether it is the same as the previous one:

- If it is the same, increment the count by 1.
- Otherwise, reset the count to 1.

At the same time, maintain another variable to track the maximum value of the count at any point.

After completing the iteration, this maximum value will represent the length of the longest contiguous repetition.
